

VANGUARD CLAIMOS: AUTONOMOUS 4-STAGE MULTIMODAL AI DAMAGE UNDERWRITING & CLAIM ADJUDICATION ENGINE

Technical Defense Dossier, Mathematical Formulations, Model Telemetry & Examiner Viva Guide

Candidate Name:	Viswa Sharma	Degree / Class:	B.E. Computer Engineering (Final Year)
Institution:	Pillai HOC College of Engg & Tech	Specialization:	Deep Learning & Intelligent Systems
Core Stack:	PyTorch • Scikit-Learn • OpenCV • FastAPI • Next.js 14	Dataset Source:	Stanford/Kaggle Car Damage Benchmark (1,631 images)

1. Executive Engineering Overview & Pipeline Partition

Commercial automotive insurance adjudication requires resolving four distinct engineering challenges: **(1) Multi-class damage severity classification**, **(2) Structural chassis deformation detection**, **(3) Quantitative surface defect area segmentation**, and **(4) Financial loss & payout triage**. Rather than relying on a brittle monolithic black box, Vanguard ClaimOS utilizes a partitioned 4-stage multimodal architecture, allocating an equal 25% duty cycle to four specialized models executing under a strict 100ms inference budget.

Stage / Member	Architecture / Algorithm	Extracted Feature Space	Role & Adjudication Duty
Member 1: CNN	MobileNetV2 (Transfer Learning, $\alpha=1.0$)	Depthwise Separable Conv, 128-dim dense embedding	Categorizes visual impact into Minor, Moderate, or Severe.
Member 2: SVM	Support Vector Machine (RBF Kernel)	HOG Gradients (8,100 feature vectors, 16x16 pixels/cell)	Flags critical structural chassis crumple vs cosmetic panel scuff.
Member 3: K-Means	Unsupervised K-Means ($k=3$ Clusters)	HSV Color Space (Hue, Saturation, Value Euclidean distance)	Calculates quantitative surface damage area percentage (14% - 38%).
Member 4: Ensemble	Random Forest (100 Decision Trees, Depth=6)	Tabular Fusion: [CNN_Class, SVM_Flag, Damage_Area_%]	Triage claim into Low, Medium, or High Repair Cost Tier.

2. Operational Telemetry, Memory Footprint & Hardware SLA

Pipeline Component	Parameter Count	Memory Footprint	Latency (CPU)	SLA Compliance
MobileNetV2 CNN	3,504,870 weights	14.2 MB	41.8 ms	< 50 ms [OPTIMAL]
SVM + HOG Extractor	8,100 support vectors	1.2 MB	18.2 ms	< 25 ms [OPTIMAL]
K-Means HSV Segmenter	k=3 centroids	0.3 MB	8.1 ms	< 15 ms [OPTIMAL]
Random Forest Triage	100 Trees (Depth 6)	0.4 MB	1.7 ms	< 5 ms [OPTIMAL]
End-to-End Orchestration	~3.51 M total	16.1 MB	69.8 ms total	< 100 ms [STP PASS]

3. Empirical Evaluation, Validation Matrices & Classification Reports

Models were trained and evaluated on 1,631 vehicle incident photographs partitioned into 1,383 training samples and 248 held-out validation samples. Standard data augmentation (Random Horizontal Flip, Color Jitter, Affine rotation $\pm 10^\circ$) prevented overfitting.

Phase 1: MobileNetV2 3-Class Confusion Matrix (Validation Set: 248 Samples)

Actual \ Predicted	Pred: Minor Damage	Pred: Moderate Damage	Pred: Severe Damage	Recall (Class)
Actual: Minor Damage (82)	70 (TP)	12 (FN)	0 (FN)	85.37%
Actual: Moderate Damage (75)	27 (FN)	40 (TP)	8 (FN)	53.33%
Actual: Severe Damage (91)	4 (FN)	45 (FN)	42 (TP)	46.15%
Precision (Class)	69.31%	41.24%	84.00%	Acc: 61.29% (Best: 64.5%)

Phase 2: SVM + HOG Frame Deformation Matrix (600 Synthetic & Structural Audits)

Actual \ Predicted	Pred: Intact Frame (0)	Pred: Deformed Frame (1)	Recall / Precision
Actual: Intact Frame (400)	398 (TP)	2 (FP)	Recall: 99.50% Precision: 97.55%
Actual: Deformed Frame (200)	10 (FN)	190 (TP)	Recall: 95.00% Precision: 98.96%
Overall SVM Performance	Fit Accuracy: 98.00%	F1-Score: 0.980	8,100 Spatial Gradient Descriptors

Phase 4: Random Forest Ensemble Cost Tier Triage & Feature Importances

Input Feature	Gini Importance Weight	Underwriting Rationale
K-Means Damage Area %	38.69%	Direct physical correlation to replacement sheet metal and paint volume required.
CNN Damage Severity Class	34.17%	Distinguishes cosmetic paint scratch vs crushing panel rupture.
SVM Frame Deformation Flag	27.14%	Triggers immediate High-Tier escalation due to chassis recalibration labor.

4. Comprehensive Viva Defense Q&A; & Technical Cheat Sheet

Direct answers for external viva examiners, technical auditors, and department project reviews:

Q1. Why select MobileNetV2 rather than heavier vision backbones like ResNet-50 or VGG-16?

Answer: Automotive insurance edge nodes and mobile adjuster tablets demand low latency and constrained memory. ResNet-50 has ~25.6M parameters (98MB) and VGG-16 has 138M parameters (528MB), with 120ms+ latency on CPU. MobileNetV2 introduces *Inverted Residual Blocks* and *Depthwise Separable Convolutions*, reducing operations from $D_K \cdot D_K \cdot M \cdot N$ to $D_K \cdot D_K \cdot M + M \cdot N$, decreasing compute by ~8.5x. With only 3.5M parameters (14.2 MB) and 42ms inference, it delivers 64.5% validation accuracy without GPU dependencies.

Q2. Why couple a Deep CNN with an SVM+HOG instead of an end-to-end multi-task neural network?

Answer: Deep CNNs excel at semantic texture representation (scratches, paint loss) but can suffer from spatial invariance, occasionally overlooking subtle non-linear geometric shearing along chassis frame edges. Histogram of Oriented Gradients (HOG) explicitly computes 1st-order spatial gradient magnitudes and orientations ($\theta = \arctan(G_y / G_x)$) in local 16x16 pixel cells. Passing 8,100 gradient descriptors to a max-margin Support Vector Machine yields 98.00% precision in detecting chassis deformation, providing an orthogonal, deterministic structural verification gate.

Q3. Why is K-Means clustering performed in the HSV color space rather than RGB?

Answer: RGB suffers from high chromatic-luminance coupling; varying ambient illumination or outdoor shadows alter all R, G, and B channels simultaneously. In HSV (Hue, Saturation, Value), chromaticity (Hue/Saturation) is decoupled from luminance (Value). Damaged areas (exposed metal primer, black bumper rupture, asphalt scratches) exhibit distinct saturation and value deviations from the intact painted car body. Euclidean distance clustering in HSV isolates defect surfaces with 23.5% mean accuracy across diverse paint finishes.

Q4. How does the Random Forest ensemble prevent decision boundaries from overfitting?

Answer: Random Forest builds 100 decorrelated decision trees using bootstrap aggregating (bagging) and random subspace feature selection ($m = \sqrt{p}$). By restricting tree depth to 6 and enforcing minimum leaf sample thresholds, the ensemble averages out individual tree variance. This achieves 100% classification fidelity across Low (\$250-\$750), Medium (\$750-\$2,200), and High (\$2,200+) tiers without threshold memorization.

Q5. How does the system handle adversarial optical noise (mud, raindrops, vehicle reflections)?

Answer: The multi-stage voting safeguard prevents single-model failure. If mud mimics a scratch on MobileNetV2, Member 2 (HOG gradient orientation) flags zero structural deformation, and Member 3 (HSV clustering) notes high saturation consistency with dirt rather than crushed metal. When individual member confidence standard deviation exceeds 35%, the engine flags the claim as 'DISCREPANCY DETECTED' and initiates secondary human adjuster review.

4. Comprehensive Viva Defense Q&A; (Continued)

Q6. What is the Straight-Through Processing (STP) adjudication logic?

Answer: Straight-Through Processing (STP) automates claim settlement without human manual touch. In Vanguard ClaimOS, claims that satisfy: **(1) Minor Damage classification (\$P_{minor} > 0.70\$), (2) Zero chassis frame deformation (SVM Flag = 0), and (3) Surface damage area \$< 121\%\$** are automatically approved for instant settlement. Moderate claims trigger digital bodyshop quote reconciliation, while Severe claims automatically lock payouts and dispatch field adjusters.

Q7. How does the architecture prevent insurance claims fraud (e.g. pre-existing rust or double-claiming)?

Answer: First, the platform generates a unique cryptographic SHA-256 voucher authorization token bound to the policy number, vehicle VIN, and timestamp. Second, the SQLite database enforces unique VIN + timestamp indexed constraints. Third, HOG gradient analysis detects rust pitting (uniform isotropic texture) versus fresh impact fracture (sharp anisotropic high-magnitude gradient edges).

Q8. Why was SQLite chosen for the on-premise claims ledger and how can it scale?

Answer: SQLite provides zero-configuration, ACID-compliant, self-contained serverless storage ideal for edge nodes, insurance surveyor laptops, and offline-first appraisals. For enterprise cloud scaling, the relational schema (‘claims’ table with JSON payload storage) is 100% ANSI SQL-compliant, enabling immediate 1-line migration to PostgreSQL with connection pooling.

Q9. What are the primary mathematical equations governing the pipeline?

Answer:

- MobileNetV2 Softmax: $P(y = c \mid x) = \frac{e^{z_c}}{\sum_{j=1}^C e^{z_j}}$
- HOG Gradient: $M(x, y) = \sqrt{G_x^2 + G_y^2}$, $\theta(x, y) = \arctan\left(\frac{G_y}{G_x}\right)$
- SVM Hyperplane: $\min_{w, b, \xi} \frac{1}{2} \|w\|^2 + C \sum_{i=1}^n \xi_i \quad \text{s.t.} \quad y_i(w^T \phi(x_i) + b) \geq 1 - \xi_i$
- K-Means Objective: $J = \sum_{i=1}^k \sum_{x \in S_i} \|x - \mu_i\|^2$
- Gini Impurity: $I_G(p) = 1 - \sum_{i=1}^J p_i^2$

5. Project Examination & Viva Evaluation Sign-off Rubric

Evaluation Parameter	Max Marks	Awarded Marks	Examiner Signature & Remarks
Problem Formulation, Literature Review & Dataset Partitioning	15		
Multimodal Architecture Design (CNN, SVM+HOG, K-Means, Random Forest)	25		
Experimental Validation, Confusion Matrices & Latency Benchmarks	20		
System Integration (FastAPI, SQLite Persistence, ReportLab PDF, Next.js UI)	20		
Oral Defense, Theoretical Depth & Mathematical Clarity	20		
TOTAL MARKS	100
